

1 Multi-dimensional arrays in MIPS

1.1 Implementing multi-dimensional arrays

Ways of implementing multi-dimensional arrays

- Row major → Most widely used.
- Column major → Not widely used.

1.1.1 Row-major way

Consider this 2D array:

```
int array[3][4];
```

This is how the array looks like:

$$\begin{bmatrix} \text{array}[0][0] & \text{array}[0][1] & \text{array}[0][2] & \text{array}[0][3] \\ \text{array}[1][0] & \text{array}[1][1] & \text{array}[1][2] & \text{array}[1][3] \\ \text{array}[2][0] & \text{array}[2][1] & \text{array}[2][2] & \text{array}[2][3] \end{bmatrix}$$

This is how the array will look like in row-major form:

| | |
|----|-------------|
| 0 | array[0][0] |
| 1 | array[0][1] |
| 2 | array[0][2] |
| 3 | array[0][3] |
| 4 | array[1][0] |
| 5 | array[1][1] |
| 6 | array[1][2] |
| 7 | array[1][3] |
| 8 | array[2][0] |
| 9 | array[2][1] |
| 10 | array[2][2] |
| 11 | array[2][3] |

Table 1: Row-Major representation of matrix array

To access the values in the array, we will use the following formula:

$$addr = baseAddr + (rowIndex * colSize + colIndex) * dataSize$$

1.1.2 Column-major way

To access the values in the array, we will use the following formula:

$$addr = baseAddr + (colIndex * rowSize + rowIndex) * dataSize$$

The array in column-representation:

| | |
|----|-------------|
| 0 | array[0][0] |
| 1 | array[1][0] |
| 2 | array[2][0] |
| 3 | array[0][1] |
| 4 | array[1][1] |
| 5 | array[2][1] |
| 6 | array[0][2] |
| 7 | array[1][2] |
| 8 | array[2][2] |
| 9 | array[0][3] |
| 10 | array[1][3] |
| 11 | array[2][3] |

Table 2: Column-Major representation of matrix array
